

## Checklist

The system is working correctly according to the given input examples. There is only a small part that I couldn't fix. The last three Zreport outputs in the example output.txt are different from mine according to Input1.txt. After checking, the devices are sorted by their shutdown time in the last three Zreport commands. After the device is shut down, this value becomes null and among the null values, the first device is the last one to shut down. However, this order is different in the example output.txt and I couldn't understand the reason for this.

I couldn't detect any other issues. My guess is that the system might produce different outputs when tested with inputs that are very different from the example inputs. Perhaps the system could encounter an error that I couldn't catch. This is a large project with many possibilities, and it's difficult to catch all of them at once. For example, my input should have three elements, but if four elements are entered, it might not produce an error. This is because there would be no issue when taking the first three. However, if my input had only two elements, the try-catch would catch this error.
